Abstract
Periampullary cancer consist of pancreatic cancer, carcinoma of ampulla of vater, distal common bile duct and duodenum. With the use of multimodality treatment, the prognosis of periampullary carcinoma has been improved. Skull (calvarium) metastasis is uncommon presentation. Only few cases of periampullary carcinoma with skull metastasis are available in English literature. Although rare, metastatic periampullary adenocarcinoma should be considered as a differential diagnosis in patients presenting with abnormal scalp swelling and tenderness. We reported a case of 48 year old female who presented with lytic expansile bone lesion with associated soft tissue mass in left parietal region with no neurological deficit 18 months after the whipple procedure.

Keywords: Periampullary Carcinom; Scalp Metastasis; Skull Metastasis

Introduction
The global annual incidence rate for carcinoma of pancreas is about 8/100,000 persons¹ and is currently the fourth leading cause of cancer mortality in the United States It is anticipated that it become the second by 2020.² Skull (calvarium) metastasis is common from malignancies like breast, lung colon, prostate, kidney and ovary.³ Gastrointestinal and pancreatic cancer rarely metastasized to brain and skull.⁴ However there are only few anecdotal reports in which ampulla of vater adenocarcinoma had metastasis to skull.⁵⁶ Here we are presenting a case of carcinoma head of pancreas with expansile osteolytic calvarial metastasis.

Case Presentation
A 48 years old post-menopausal female was diagnosed with periampullary carcinoma, underwent whipple surgery and feeding jejunostomy,[Fig. 1] Histopathology was suggestive of moderately differentiated adenocarcinoma, R0 resection with node positive. Case was discussed in multidispilanry clinic and planned for adjuvant chemotherapy. She had received adjuvant chemotherapy with Gemcitabine and Cisplatin till Sept 2014 and was kept on follow up. After 11 months of follow up, she developed swelling on left side of forehead, which was progressive increasing in size with mild pain. No complain of discharge from swelling, vomiting, headache, seizures, decrease of vision. On examination 5x5 hard fixed swelling present on left side of forehead with tense shiny skin, non-tender, temperature over the swelling not raised. Biopsy from the swelling was suggestive of metastatic carcinoma. CECT Scan of skull showed permeative lytic expansile bone lesion with associated soft tissue mass approximately 4.6X3.5 cm in left parietal region possibly metastasis. CECT thorax and abdomen was revealed heterogenous enhancing irregular soft tissue mass esion in the retroperitoneum closely abutting right renal vessels approximately 2.5X2.2 cm suggestive of recurrent lesion with norma choedocho-jejunual, gastro-jejunal and pancreatico-jeuna anastomosis. Patient then received palliative radiotherapy to the skull lesion and is now on palliative chemotherapy. Good palliation was achieved.

Discussion

Periampullary cancer consist of pancreatic cancer, carcinoma of ampulla of vater, distal common bile duct and duodenum. Periampullary cancer are usually managed by radical operative procedures in early stages. However 80% of patients present with disease that cannot be cured with radical surgery. In a study by Lee and Tatter, patients with carcinoma pancreas and periampullary cancer invariably present with metastasis to abdominal lymph node, liver and lung. Cutaneous metastases is present in 0.7% to 9% of all patients with cancer, and is common in breast, lung, and colon cancer but are uncommon in pancreatic cancer. In pancreatic carcinoma cutaneous metastasis are usually multiple and are confined to periumbilical region. Isolated non umbilical metastasis are uncommon. Pancreatic cancer with cutaneous metastasis to the scalp is rare.

So far to the best of our knowledge, there are only 7 cases of pancreatic cancer with scalp metastasis which are documented in literature. Out of these there are only 5 cases including present study, in which skull is involved. In a study by Miyahara et al., 20 patients out of 22 reported with cutaneous metastasis prior to diagnosis of pancreatic cancer. In 11 of these, skin involvement was the first presentation.

Hopf S et al reported a case of cancer of ampulla of vater with right frontal skull metastasis 5 years after pylorus preserving pancreatoduodenectomy. In another study, by Jeon JY et al 65 year old Koren man presented with parietal scalp swelling after whipple procedure. Aydin et al also reported a case of a 65-year-old woman, presented with painless frontoparietal scalp swelling which developed within three months and is the first presenting symptom of pancreatic adenocarcinoma. In the present study, patient of periampullary carcinoma developed skull metastasis 18 months after the curative whipplies procedure, with no neurological deficits other than mild headache and scalp swelling despite adjacent dura is involved and underlying cortex is compressed.

Conclusion

With the use of multimodality treatment, the prognosis of periampullary carcinoma has improved, although rare, metastatic periampullary adenocarcinoma should be considered as a differential diagnosis in patients presenting with abnormal scalp swelling and tenderness.
