Abstract
Pulmonary tuberculosis with multi-drug resistant Mycobacterium tuberculosis is a major cause of concern in the developing countries. The present study was carried out to study the prevalence of multi-drug resistant tuberculosis (MDR-TB) in clinical isolates at Sir Sunderlal hospital in Banaras Hindu University, Varanasi, India, which is a tertiary care hospital. One hundred and eighty nine (189) sputum samples were collected from clinically suspected cases of tuberculosis and subjected to Ziehl-Neelsen stains (ZN) and culture on Lowenstein-Jensen (LJ) medium and 46 cultural isolates were obtained and subjected to drug susceptibility against Isoniazid (INH) and Rifampicin (RIF). A total of nine (19.5%) isolates were found to be resistant against INH and two strains (4.5%) was found to be resistant against both RIF and INH. No strain was found to be resistant against Rifampicin alone. The present study revealed the presence of 4-6% of multi-drug resistant M. tuberculosis infection in patients attending Sir Sunderlal hospital in Banaras Hindu University. This emphasizes the need for strengthening laboratory services for timely diagnosis of MDR TB.

Keywords: Pulmonary tuberculosis, drug susceptibility, Isoniazid, Rifampicin

Introduction
Tuberculosis continues to be a major health problem in India accounting for an estimated 30% of global tuberculosis burden. At present about one million new smear positive cases are added annually to this figure. Although drug resistant tuberculosis has frequently been encountered in India, the available information is localized. Much of drug resistance encountered in India is diagnosed presumptively based on patient’s lack of clinical improvement or relapse of symptoms.

Preparation of drug containing LJ medium
The drug concentration for INH and RIF should be 0.2 μg/ml and 40 μg/ml of the medium respectively, to get 1% critical proportion to determine the drug resistance in this method.

Standardization of inoculums
The various dilutions of inoculums: Neat 107-108, 10-2 and 10-4 for inoculation of drug containing
medium are prepared in comparison to McFarland’s No1 Standardization of inoculums.

**Specimen inoculation**

For each isolate a total of seven LJ medium slopes (with and without drugs) were inoculated. A loopful of inoculums was streaked onto the LJ media. With neat concentration of 107 to 108 inoculums, one drug free LJ medium is inoculated. With 10-2: One drug free, one INH (0.2 μg/ml) and one RIF (40μg/ml) containing LJ media are inoculated. Similarly with 10-4: One drug free, one INH and one RIF containing LJ media are inoculated.

**Incubation and Reading**

Inoculated LJ slopes are incubated at 37°C for 42 days and were examined on day 28 and 42 for colonies. Slopes which were positive for growth by 28th day and found to have confluent growth on both drug free and drug containing media, were discarded considering them as resistant strains. If the results on28th day were “sensitive” for the two drugs or negative for growth, a second reading was taken on 42nd day.

<table>
<thead>
<tr>
<th>Presence of growth is recorded as</th>
<th></th>

<tbody>
<tr>
<td>Confluent growth</td>
<td>= 3 +</td>
</tr>
<tr>
<td>More than 100 colonies</td>
<td>= 2 +</td>
</tr>
<tr>
<td>Countable number of colonies</td>
<td>= 1 - 100 colonies</td>
</tr>
</tbody>
</table>

When the number of colonies in 10⁻¹ dilution is less than five colonies, the next larger inoculums 10⁻² was read for colonies. Colonies were counted only on the slopes that were readable (up to 100 colonies on the slope). More than 100 colonies was taken as confluent. Dividing the number of colonies in drug containing slopes by that in drug free slopes gives the proportion of resistant bacilli existing in the strain. Below 1% of critical proportion the strain was considered as sensitive and above 1% as resistant. In case growth on the control media is poor even after six weeks i.e., few or no colonies on the 10⁻⁴ bacterial dilution, the tests were repeated.

**Results**

This prospective study was done in the Institute of Medical Sciences on 46 cultural isolates of *M. tuberculosis* isolated from 189 sputum samples of suspected tuberculosis patients attending to Tuberculosis unit of Sir Sunderlal hospital (tertiary care hospital) from June 2014 to December 2015. Of the total 46 isolates 33 (71.5%) were from male patients and 13 (28.5%) were from female patients. The 46 isolates of *M. tuberculosis* were subjected to drug susceptibility testing by economical variant of proportion method. Thirty five (35) isolates were sensitive to both INH and RIF (76%). Nine strains were resistant to INH alone (19.5%). Only two strain was resistant to both INH and RIF (4.5%).

**Discussion**

MDR-TB has been influencing the world economy as well as the health of individuals and their family members. The emergence of XDR-TB and TDR-TB together put a challenge to the mankind. Various reasons are proposed for the emergence of drug resistant strains. The active participation of government as well as non-governmental organizations is lacking in some under developed and developing countries like Russian federation, India and China. Unavailability of proper laboratory setup at the gross root level was the most probable reason. In these countries there is scaling up of facilities at tertiary care centers of various states but at the primary care centers these facilities were still lacking. TB as well MDR-TB incidence is still increasing especially in the present HIV era.

In the present study 186 sputum samples were collected and a total of 46 positive isolates were obtained and the others excluded due to smear negativity and growth of atypical mycobacterium. The forty six (46) isolates were subjected to drug susceptibility testing. Nine (9 i.e.; 19.5%) isolates showed resistance to single drug (INH). Two (2 i.e.; 4.5%) isolates showed multi drug resistance (INH+RIF). In 2003 WHO-IUAT (International Union Against Tuberculosis) had reported single drug (INH) resistance in 15.2% cases and multi drug (INH+RIF) resistance in 0.5%, (10) which is higher in the present study which shows single drug resistance of 19.5% and multi drug resistance in 4.5%.

Almeida and Rodrigue in 2002 reported the incidence of multi drug resistance in 150 consecutive Mycobacterium tuberculosis isolates obtained from a rural center (in Sakawar, India) and an urban tertiary care center (in Mumbai, India). The study highlights an alarmingly high percentage of multi drug-resistant *M. tuberculosis* isolates in Mumbai (51%) as compared with that at the rural center (2%). The present study of multi drug resistance correlates with the rural center value. Deivanayagam and Rajasekaran studied total of 1000 sputum samples from which 618(61.8%) isolates obtained. Four hundred ninety five (495) samples were resistant to any one drug. MDR- TB was detected in 339 patients (54.84%). Present study results were on a lower side.

Cohn and Bustriore viewed and tabulated 63 surveys of resistance to anti-tubercular drugs that were performed between 1985 and 1994. The rate of primary resistance to INH was 0-16.9%, RIF was 0-3.0%, streptomycin was 0.1%-23.5%, ethambutol was 0-4.2%. The highest rates of multi drug resistant tuberculosis has been reported in Nepal 48.0%, Gujarat, India 33.8%, New York City 30.1%, Bolivia 15.3%, Koria 14.5%.

Saillour and Robert studied the factors related to the outcome of 51 cases of multi-drug resistant tuberculosis (MDR-TB) in 1994 reported to the French National Reference Center were retrospectively
analyzed. The patients (median age, 45 yr) were mainly male (75%). Seventeen (17 i.e., 33%) isolates were reported as resistant only to INH, 1 RIF, 18 (35%) streptomycin (SM), 4 (8%) to ethambutol (EMB), and 12 (24%) to both SM and EMB. Hassan and Musa conducted study for a total of one hundred (100) sputa collected from new untreated and epidemiologically unrelated patients from March 2006 to March 2007. The study reported multi drug resistance as 66.7% and single drug (INH) resistance 76.9%. The present study showed values on a lower side. Affolabi and Adjaiga studied a total of 470 isolates of *M. tuberculosis complex* from pulmonary tuberculosis (TB) patients. Of these 244 were from new cases and 226 from previously treated cases. Drug susceptibility testing was performed using the proportion method. They reported MDR in 1.6% new cases. No relation was found between human immuno-deficiency virus co-infection and anti-tuberculosis drug resistance. The present study correlates with this value.

Zwolska and Kopec conducted a prospective survey, collected M. tuberculosis strains from 3970 tuberculosis patients (2976 newly diagnosed cases and 994 previously treated patients) confirmed by culture between November 1996 and October 1997. Drug susceptibility testing (DST) to Isoniazid (INH), streptomycin, ethambutol and rifampicin (RMP) were performed on Lowenstein-Jensen medium according to the proportion method and using the radiometric Bactec 460 TB system. They reported single drug INH resistance as 2.6%, RIF’s resistance as 0.7% and multi drug resistance as 0.6%.

In another study conducted by Katoch and Malhotra at Jaipur during 1997-99 where 164 samples were processed and 122 isolates were subjected to DST and the following results were obtained. Drug resistance towards RIF was 3/44 isolates (6.8%) and to INH was 6/44 isolates (13.6%) and two (2) isolates showed multi drug resistance (INH+RIF). Another study by Krishnamurthy and Rodrigues at Mumbai by means of phage assay and BACTEC 460 TB analyzed 85 samples. The following results obtained 70 were resistant to RIF and 12 were sensitive. Though in the present study for DST (Drug susceptibility testing) it requires 6-8 weeks for isolation and 6 weeks for DST the proportion method is economical than above said phase assay and BACTEC 460 TB.

In another study conducted by Paramasivam and Venkataramanin North Arcot (Tamil Nadu) and Raichur (Karnataka) with sample size of 320 from North Arcot and 314 from Raichur the following results were obtained. In North Arcot mono resistance to INH-23.4%, to RIF-2.8% and multi drug resistance 2.8% and in Raichur for INH, RIF and multi drug resistance (INH+RIF) were found to be 18.7%, 2.5% and 2.5% respectively.

In a study conducted by Mahadev and Kumar in Hoogli in West Bengal and Mayurbhanj in Orissa for detection of drug resistance during August 2000 to July 2001 where 350 smear positive samples from Hoogli and 343 smear positive samples from Mayurbhanj microscopy centers were collected. Pure isolates were obtained after processing the samples and subjected to DST. The following results were obtained. Multi drug resistance (INH+RIF) seen in one (01) sample in both the areas and mono resistance of INH seen in 6 samples from Hoogli and 3 samples from Mayurbhanj, which correlates with the present study which shows single drug resistance in 9 isolates (19.5%) and multi drug resistance (INH+RIF) in two (02) isolate (4.5%). They also studied resistance pattern of other drugs like Ethambutol and streptomycin.

**Conclusion**

The present study emphasizes the need for strengthening laboratory diagnosis of MDR-TB and XDR-TB, infection control methods to avoid transmission to health care workers and in Community. Research to be promoted for development of new diagnostic methods, drugs and vaccines for early detection and management of MDR-TB.
