Abstract

Introduction: Urinary Tract Infection (UTI) remains the most common bacterial infection in human population. The prevalence of UTI is much higher in females as compared to males. The present study was planned with the aim to find out prevalence of uropathogens and their antibiotic resistance pattern in reproductive age group females.

Materials and Methods: The present study was carried out in department of microbiology, Santosh Medical College and Hospital, Ghaziabad from Jan. 2018 to May 2018. Total 100 urine sample were processed for culture and sensitivity testing. Isolation of organism were done by inoculation of samples on Mac-Conkey Agar and Blood Agra media. After 24 hour of incubation at 37^o C, each isolates were identified on the basis of morphology of colony in culture media, Gram stain, motility and biochemical reactions. Antibiotic sensitivity testing were carried out on Mueller Hinton Agar by Kirby Bauer method.

Results: The prevalence of uropathogen was found 36%. The Gram-negative bacteria were most common isolates in comparison to Gram-positive bacteria. E. coli was the most common isolates followed by S. saprophyticus. Gram-negative organism were found more sensitive to Amikacin, Piperacillin Tazobactam, Ampicillin sulbactam, Cefoperazone sulbactam and Nitrofurantoin. Gram-positive bacteria were found more sensitive to Piperacillin Tazobactam, Tetracycline, Ampicillin sulbactam and Linezolid. E. coli were found more sensitive to Amikacin, Ampicillin sulbactam, Piperacillin Tazobactam and Cefoperazone sulbactam.

Conclusion: Changing antimicrobial resistance pose challenge in treating urinary tract infections. Appropriate and judicious selection of antibiotic would limit the emerging drug resistant isolate in the future to treat this clinical condition successfully.

Keywords: Urinary Tract Infection, UTI, Uropathogens, reproductive age group females. Pregnant women, Antibiotic resistance, E. coli.

Introduction

Urinary Tract Infections (UTI) frequently occur in both community and hospital environment are of the most common bacterial infections in humans. The outcomes of urinary tract infections are increase hospitalization, increase patient treatment cost and mortality.¹ Bacteria can invade and cause UTI via two major routes ascending and hematogenous pathway. Ascending route is most common route of infection in females. Urinary tract infections are characterized as either upper or lower UTI primarily on the basis of anatomical location of infection. The lower UTI affecting the bladder and urethra and the upper UTI affecting the ureter and kidneys mainly.

Women are at three times greater risk for UTI than man because of short, straight anatomy of the urethra, and termination of female urethra beneath the labia resulting in colonization by colonic gram negative bacilli.² Most of the UTI are caused by gram-negative bacteria like E. coli, Proteus species, Klebsiella species, Pseudomonas aeruginosa, Acinetobacter, Serratia and Morganella morganii. UTI also caused by gram positive bacteria like Enterococcus, Staphylococcus specially coagulase negative Staphylococci and Streptococcus agalactiae.³

E. coli are one of the most prevalent pathogens among gram-negative bacteria capable of causing complicated and uncomplicated UTI.⁴ UTI during pregnancy leads to low birth weight babies, increase perinatal mortality and premature births along with acute and chronic sequelae in mothers.⁵ Diagnosis and definitive treatment of UTI mainly based on bacteriological culture and antibiotic sensitivity. In past

decade, indiscriminate use of antibiotics resulted in word wide rise of multidrug resistance cases.⁶

Hence, present study planned to find out the prevalence of urinary pathogens and their antibiotic resistance pattern in reproductive age group females to provide better cost effective treatment to female patients.

Materials and Methods

A cross sectional study was carried out in the department of microbiology, Santosh Medical College and Hospital, Ghaziabad from January 2018 to May 2018. A total of 100 urine samples were collected from female patients clinically suspected of urinary tract infection. The women in reproductive age group 18 to 45 years with history of urinary tract infection were included in the study and only one sample was collected from each patient. The exclusion criteria were leaky or dirty container, delay in transportation of sample more than 2 hours, previous history of antibiotics, surgery or operative procedure. Midstream clean catch urine samples were collected and transported to microbiology laboratory for processing. Urine culture and antibiotic susceptibility testing was performed in laboratory. The urine culture was done using a sterile calibrated loop of 4 mm diameter delivering 10 microliter volume of urine. A loopful of well mixed uncentrifuged urine was inoculated on the Mac-Conkey Agar and Blood Agar media plates. All plates were incubated at 37^o C aerobically for 24 hours.⁷ The bacterial growth was identify by Gram stain, motility and a set of biochemical test including catalase, coagulase, oxidase, indole, methyl red, Voges Proskauer, citrate, urease and triple sugar iron media.

Antimicrobial susceptibility testing was performed by using Kirby Bauer disc diffusion method as described by the national committee for clinical laboratory standard (presently called clinical laboratory standard institute).⁸ Interpretation as sensitive or resistant was done on the basis of diameter of zone of inhibition of bacteria growth on Mueller Hinton Agar plate as recommended by Hi Media disc manufacturer. Antibiotic discs used for susceptibility testing for gram negative bacteria were Amikacin (30 µgm), Ampicillin sulbactam (10 / 10 µgm), Ceftriaxone (30 µgm), Cefotaxime (30 µgm), Ciprofloxacin (5 µgm), Cefixime (5 µgm), Ceftazidime (30 µgm), Cefoperazone sulbactam (75 / 30 µgm), Co-trimoxazole (25 µgm), Norfloxacin (10 µgm), Nitrofurantoin (300 µgm), Ofloxacin (5 µgm), Piperacillin tazobactam (100 / 10 µgm) and Imipenem (10 µgm). Antibiotic disc used for gram-positive bacteria includes Ceftazidime (30 µgm), Ciprofloxacin (5 µgm), Cloxacillin (100 µgm), Co-trimoxazole (25 µgm), Gentamicin (10 µgm), Norfloxacin (10 µgm), Nitrofurantoin (300 µgm), Penicillin (10 U), Piperacillin tazobactam (100 / 10 µgm), Tetracycline (30 µgm), Vancomycin (30 µgm) and Linezolid (30 µgm). Data collected and analysis was done using appropriate statistical methods.

Results and Discussions

In present study, the prevalence of uropathogens in reproductive age group female was found to be 36% (Table 1). B. Shanthi et al. (2018)⁹ found the higher prevalence rate due to their large sample size. The maximum number of cases were found in the age group 18 – 30 years and minimum number of cases were found in the age group 31 – 45 years (Table 2). The reason being women in this age group are more sexually active and more prone to develop UTI probably due to characteristic anatomy of the urethra and the effect of normal physiological changes that affects the urinary tract – short urethra, its close proximity to the anus, urethral trauma during intercourse, dilatation of urethra and stasis of urine during pregnancy.^{10,11}

Out of 100 cases, 11 females were found pregnant and 89 were found non-pregnant. All 11 pregnant women were found culture positive due to a number of factors including urethral dilation, increase bladder volume and decrease bladder tone, along with decrease urethral tone, which contributes to increase urinary stasis and vesicoureteral reflex and up to 70% of pregnant women develop glycosuria, which favors bacterial growth in the urine.¹²

Gram-negative bacteria dominated over gram-positive bacteria as the etiological agent for UTI as shown in Table 3. *E. coli* was the most common isolates both in non-pregnant and pregnant women followed by *Staphylococcus saprophyticus*. The other micro-organisms isolated were *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Proteus mirabilis*, *Citrobacter freundii*, *Enterococcus faecalis*. Out of total isolates, 50% were *E. coli* and 19.4% were *Staphylococcus saprophyticus*. Similar results were found by Goyal Ankur et al. 2015¹³ Agersew Alemu et al. 2012¹⁴ and Geeta Gupta et al. 2019.¹⁵

The gram-negative bacteria were found more sensitive to antibiotics Amikacin, Piperacillin Tazobactam, Ampicillin sulbactam, Cefoperazone sulbactam and Nitrofurantoin (Table 4). Similar results were found by B. Shanthi et al. (2018)⁹ and Obiogbolu et al. (2009).¹⁶ The gram-positive bacteria were found more sensitive to antibiotics Piperacillin Tazobactam, Tetracycline, Ampicillin sulbactam and Linezolid (Table 5). The most effective antibiotic for the *E. coli* was found to be Amikacin and Ampicillin sulbactam, Iram Shaifali et al. (2012)¹⁷ observe Nitrofurantoin followed by Amoxicillin, Nalidixic Acid and Co-Trimoxazole were sensitive. The most effective antibiotic for the *S. saprophyticus* was Tetracycline and Levofloxacin. Adedeji BA et al. (2009)¹⁸ found Gentamycin and Ofloxacin were the most active antibiotics and isolates showed high resistance to Co-Trimoxazole and Amoxicillin, The reason behind different antibiotic susceptibility pattern of isolates from other studies because sensitivity varies widely by region, OPD and IPD patients included in the study.

Table 1: Showing growth pattern among pregnant and non-pregnant women

S. No.	Growth	Pregnant	Non-Pregnant	Total
1	Present	11	25	36
2	Absent	-	64	64
Total		11	89	100

Table 2: Showing age group wise distribution of pregnant and non-pregnant women

S. No.	Age Group (Yrs)	Pregnant	Non-Pregnant	Total
1	18 – 30	11	25	36
2	31 – 40	-	35	35
3	41 – 45	-	29	29
Total		11	89	100

Table 3: Distribution of isolated micro-organisms in culture

S. No.	Micro-organism	No. of Women		Total
		Pregnant	Non-Pregnant	
1	E. coli	06	12	18
2	S. saprophyticus	04	03	07

10	Ciprofloxacin	9 (69.23)	1 (7.69)	1 (7.69)

Conclusion

The present study raised awareness regarding high vulnerability of women in reproductive age group for urinary tract infections. The pregnant women were found more prone to develop UTI in comparison to the non-pregnant women. The study provide information regarding uropathogens and their antibiotic susceptibility pattern. Gram-negative bacteria were found more common isolates in comparison to gram positive bacteria causing UTI. Analyzing antibiotic susceptibility pattern of uropathogens will help to overcome the therapeutic dilemmas and to guide in selection of appropriate antibiotics for empirical treatment to the patients
