Abstract
3D printing has been acclaimed as a disruptive technology which will change manufacturing. This technology is used in various fields such as aerospace, defense, art. Recently it has become a subject of great interest in virtual surgical planning. The technology has a particular resonance with dentistry. It has become of great importance with advancement in 3D imaging and modeling technologies such as CBCT, intraoral scanning and CAD CAM in dentistry. Uses of 3D printing include the production of drill guides for dental implants, the production of physical models for prosthodontics, orthodontics and surgery, the manufacture of dental, craniofacial and orthopedic implants and the fabrication of copings and frameworks for implant and dental restorations. This paper reviews the types of 3D printing technologies available and their various applications in dentistry and in maxillofacial surgery.

Keywords: Three-dimensional printing, Rapid additive manufacturing, Selective laser sintering, Stereo lithography

Introduction
3D printing is also known as additive manufacturing (AM), rapid prototyping, layered manufacturing or solid free form fabrication. It is the process in which multiple layers of material is added one by one under computer control to create three-dimensional object. The key idea of this innovative method is that the three dimensional model is sliced into many thin layers and the manufacturing equipment uses this geometric data to build each layer sequentially until final desired product is complete. It all starts with creation of a virtual design of the object. Scanner may be used to scan buildings, rock formations, etc., to produce a 3D model. The 3D model is sliced and then it is ready to feed into the 3D printer of compatible brand and type. This can be done via USB, SD or Wi-Fi. When a file is uploaded in a 3D printer, the object is ready to be 3D printed layer by layer. The 3D printer reads every slice (2D image) and creates a three dimensional object. Objects of any geometry can be made by this technology. This is what we call slicing.

3D printing over CAD CAM technology
1. Subtractive methods such as CAD CAM has some limitations in relation with 3D printing.
2. Large amount of raw material is wasted because of unused portions of the mono-blocks which are discarded after milling and recycling of the excess ceramic is also not feasible.
3. Milling tools are prone to heavy abrasion and wear which shortens their cycling time.
4. Due to brittle nature of ceramic microscopic cracks can be introduced during the process of machining.

Stereolithography
History of Stereolithography dates back to 1980 and was introduced by Charles Hull. Principle of making solid objects involves successive printing of thin layers of UV curable photopolymer layer by layer. It is used to make implant surgical guides because of high mechanical strength, obturators, surgical stents, duplication of prosthesis and burn stents. The curing time and the thickness of the layer polymerized is affected by the dynamics involved in the entire procedure. The kinetics can be controlled by the power of the light source, the scanning speed and the chemistry and amount of the monomer and photo initiators. In addition, UV absorbers can be added to the resin to control the depth of Polymerization. The main disadvantage of SLA is the scarcity of biocompatible resins with proper SLA processing properties. Additional challenges are the use of photo initiators and radi cals which may be cytotoxic (with long processing time), entrapment of unreacted monomer and residual photo initiator, and inability to create compositional gradients along horizontal planes.

Fused Deposition Modelling
Fused Deposition Modelling developed by Schott C Sump. A thermoplastic filament material is extruded through a nozzle controlled by temperature and the material hardens immediately (within .1 sec) after extrusion. Th
The motion of the nozzle head is controlled by a processor and traces and deposit the material in extremely thin layer on to a subsidiary platform. Materials such as acrylonitrile butyrate styrene (ABS), polycarbonates and poly sulphones are used. Building complex geometries usually necessitates the usage of a second extruder – for example, might extrude a water soluble support material. Accuracy will depend upon the speed of travel of the extruder, as well as the flow of material and the size of each ‘step’. This is the process that is used by most low cost ‘home’ 3D printers. It allows for the printing of crude anatomical models without too much complexity, for example, printing an edentulous mandible. (6,7) (Fig. 2)

**Selective Laser Sintering**

This technology has been brought into usage since mid-1980s and was developed by university of Texas. A fine material powder is fused by scanning laser, to build up structures incrementally. As a powder bed drops down, a new fine layer of material is spread uniformly over the surface. A high (60μm) level of resolution may be obtained. No support material is required as the structures that are printed are supported by the surrounding powder. (8) Production of facial prostheses makes use of polymers scaffolds (poly amide or poly Caprolactone). Selective laser sintering is used in fabrication of anatomical study models, cutting and drilling guides, dental models, and also for engineering/design prototypes. (9) Advantages are ease of autoclavability of the materials used, full mechanical functionality of the printed objects, lower cost materials if used in large volume. Disadvantages are powders are messy with increased inhalation risk, technology is expensive, and significant climatic conditions such as compressed air are required. (9,10) (Fig. 3)

**Photopolymer Jetting**

- This technology uses either a stationary platform and dynamic print head or a stationary print head and dynamic platform. Light sensitive polymer is jetted onto a build platform from an inkjet type print head, and cured layer by layer on an incrementally descending platform. A support structure is laid down in a friable support material. A wide range of resins and waxes for casting, as well as some silicone-like rubber materials can be printed. This technology gives the resolution of approx.16 microns and gives the easy access for making complex and fine detailed objects. (1)

- They are useful for printing dental or anatomical study models. Implant drill guides may be quickly and cheaply produced with this technology as they are less bulky. 3D Jet printers may have a single print head like a computer printer, or they may have multiple heads to cover the width of the working platform. Either the print head moves across the working platform, or the platform moves back and forth under stationary print head(s). The 3D systems and printers use a UV lamp or a light source to harden the resin or wax after each layer is jetted. (1,6) Advantages are this technology is fast and cost effective, resolution is high, high-quality finish is possible. Disadvantages are tenacious support material can be difficult to remove completely, support material may cause skin irritation, cannot be heat sterilised, materials cost is high. (3,6) (Fig. 4)
Recent Trends of 3-D Printing in Dentistry- A Review

Reeta Jain et al.

Conclusion

There is huge impact of 3D imaging and modelling, and CAD technologies on all aspects of dentistry. With the help of digital data it is possible to make accurate, precise and complex geometrical forms in a variety of materials, locally or in industrial centers through 3 dimensional printing. Although everything we make for our patients can be made by a 3D printer, but still single technology is not sufficient to fulfill all the needs of our patient. Recent advances have an ability to produce lower stiff ness scaffolds with high resolution features that allows its application in soft tissue engineering. The technology gaining importance also in the fields of orthodontics and restorative dentistry with the increase in usage of intraoral scanning systems.

Different 3D printing techniques have become imperative in maxillofacial and implant surgery, to assist the complex treatment planning by constructing virtual anatomic models. It is widely acknowledged that surgery may be less invasive and more predictable with the use of surgical guides printed in resins (commonly) or autoclavable nylon. With the evolution of 3D printing it has become possible to replicate desired geometry without an expensive mold and tooling which were not feasible with conventional techniques. 3D printers are becoming accessible and affordable but the cost of running, materials, maintenance, and skill of operators must be strongly followed. 3D printing takes the efficiencies of digital design to the production stage. The congruence of scanning, visualization, CAD, milling and 3D printing, along with the professions innate curiosity and creativity make this an exceptionally exciting time to be in dentistry.
