Abstract
Various studies in literature worldwide report high prevalence of Early Childhood caries (ECC). Traditional restorative methods for ECC are not always affordable or possible, as it require patient cooperation for desirable outcome. Silver diamine fluoride (SDF) was first promoted in Japan in late 1960’s. It is painless and simple to use for young children or patients with special needs. When SDF is applied on carious lesions, the fluoride enhances remineralization and the silver ions act as an antibacterial agent and inhibit the growth of cariogenic biofilms. SDF also preserves the dentin collagen from further degradation. SDF at 38% has been used mostly in various countries.

Keywords: Dental caries, Fluoride, Public health tool.

Introduction
Early childhood caries is an infectious, and transmissible disease of teeth affecting young children caused by various factors and is related with susceptible, uninsured, and financially weak populations.1 It is also the most prevalent condition included in the 2015 Global Burden of Disease Study, ranking 12th for deciduous teeth affecting 560 million children.2 Untreated decay in very young children can lead to increased risk of caries in other deciduous and permanent teeth, missed school hours, pain, and infections; costly emergency treatments; due to widespread decay and the associated requirement for general anesthesia; and limited growth as well as development.3 Therefore, untreated caries and underutilization of dental services are two most prominent public health problems for children in developing and undeveloped nations.4

It is essential to search an efficient, affordable method of treating dental caries in preschool children who are at high risk of caries and with restricted access to dental care to decrease the burden of untreated caries.4 The conventional management for a decayed tooth involves removal of infected and deminerlized tooth structure and subsequent replacement with a filling material.5 Additionally, management of dental caries can be difficult and may require highly developed skill of the dentist as well as extensive instrumentation and restoration cost. Also, good cooperation from patient is mandatory. This is especially difficult in case of very young children due to their limited adaptive capacity. Hence, managing a carious tooth in such children can be a riddle for the provider. In such cases, arresting caries treatment has been proposed to manage untreated dental caries.6 In recent times, SDF has been popularized for its capability to stop the caries progression and concurrently arrest the formation of new carious lesions.7 Also, SDF can be used in children who are too young to have their carious teeth restored by traditional methods. In addition, SDF application can be an affordable way of managing dental decay in many children from low income families or living in areas where there is limited access to dental service provider.

History
Japanese used silver as tooth cosmetics to prevent dental caries since 1000 years.8 In 1891, silver amalgam and nitric acid was used on carious teeth and had caries arresting properties.9 Silver nitrate was directly applied to carious cavities with analogous outcomes, and it was termed as Howe’s solution, which was used for caries inhibition.10 In Western Australia, 40% silver fluoride (AgF) was applied as the treatment for deep dental caries in primary teeth at school dental care services.11

Till late 1960s and 1970s, SDF was not much exposed to other parts of the world other than Japan. Since 1960’s, it was established as a therapeutic agent by the Central Pharmaceutical Council of the Ministry of Health and Welfare in Japan for dental treatment.11 For past few decades, SDF has also been in used in Australia12 and China13 to prevent dental decay. SDF has been used in many community dental health programs in various concentrations has been used in Argentina, Brazil and Spain; and additionally community health programmes were designed for sub-Saharan Africa and for other countries of Africa.14 Although an article in an American journal published in 1995 reported that there were health care providers in Southern California who applied SDF to seize caries progress in young children with early childhood caries.15 However, SDF was not commonly available in some countries of Europe and the USA. In 2014, SDF was approved by the US Food and Drug Administration for management of tooth hypersensitivity.7
Though its extensive use started in China in start of 21st century as a caries arresting agent in school going children. From 2005 to 2009 in Australia, a series of in vitro studies were conducted and proved effect of SDF on Streptococcus mutans and dental bio-film as a caries arresting and antimicrobial agent respectively. In Yee et al. in Nepal and 2009 Braga et al. in US used SDF as caries arresting agent. In 2013, SDF was used to prevent root caries in elderly. Studies were conducted in India providing literature of successful use of SDF as a caries arresting agent. A study in 2018 found that SDF was successful in arresting active caries in primary teeth of young children in USA and was also well received by their parents. Still, many studies are being conducted in various countries of the world to establish SDF as an aid for the dental public health community professionals to address dental caries in at-risk populations.

SDF versus Silver Fluoride
Silver fluoride (SnF₂) is a neutral colored solution having silver ions and fluoride ions. It is highly alkaline (pH = 11), which requires a two-stage application procedure using SnF₂ as a reducing agent. SDF is proved to be more non reactive and can be maintained at a constant concentration. SDF is comparatively less alkaline (pH = 8-9) than AgF and does not need a reducing agent.

Although SnF₂ is much more soluble in water than the other silver halides, it forms colourless cubic crystals. SDF is formed of ammonia and SnF₂. The ammonia ions coalesce with the silver ions to generate a complex ion called the diamine–silver ion, [Ag(NH₃)₂]⁺. Construction of these diamine silver ions is a reversible reaction and is very stable.

While AgF is not easily accessible, though SDF is widely available as 38% solution in a commercial preparation and is available in Japan as Saforide (Toyo Seiyaku Kasei Ltd, Osaka, Japan). Saforide has 380 mg water-soluble SDF in 1 ml colourless aqueous solution, or about 44,800 ppm of fluoride ions. SDF is commercially available in South America as Fluoroplant (LaboratoriosNaf, Buenos Aires, Argentina) and Safluoride di Walter in 10% solution (Polidental, Rio de Janeiro, Brazil). A 38% SDF solution is also available in Australia (Creighton Pharmaceutical, Sydney, Australia). In India, it is available in 38% concentration by brand name FAgamin.

Mechanism of Action
There could be following possible mechanisms of action of SDF against caries:
1. The first mechanism may be the occlusion of dentinal tubules with silver. According to Shimizu, when SDF is applied on dentine, its dye permeability reduced and electric resistance enhanced. He also reported that silver and its compounds from SDF application blocked the diffusion of acid and invasion of microorganisms into the dentinal tubules. It also inhibited the further growth of microorganisms by oligodynamic action of silver. Additionally, obturation of the dentinal tubules decreased the surface area of dentin, which may be attacked by caries. It has also been seen that the use of 38% SDF repressed demineralization and preserved collagen from degradation in demineralized dentin.

2. The other mechanisms could be the cariostatic action of products produced by reaction between SDF and minerals of the tooth. The fluoride present in amplified the resistance of the dentin to action of acid resulting in reduced penetration of acid into inner dentin. When SDF is applied to dentin under in vivo conditions, its fluoride ions penetrated to a depth of 50–100 μ. It has been proved that SDF (Ag(NH₃)₂F) reacts with hydroxyapatite (HA) of tooth to release calcium fluoride (CaF₂) and silver phosphate (Ag₃PO₄), resulting in hardening of affected dentine.

A basic chemical reaction is shown below:

\[
\text{Ca}_{10} (\text{PO}_4)_6(\text{OH})_2 + \text{Ag}(\text{NH}_3)_2 \rightarrow \text{CaF}_2 + \text{Ag}_3\text{PO}_4 + \text{NH}_3\text{OH}
\]

\[
\text{CaF}_2 \rightarrow \text{Ca}^{++} + 2\text{F}^-
\]

\[
\text{Ca}_{10} (\text{PO}_4)_6(\text{OH})_2 + 2\text{F}^- \rightarrow \text{Ca}_{10}(\text{PO}_4)_6\text{F}_2 + 2\text{OH}^-
\]

The Ag₃PO₄ that is formed on the tooth is insoluble to acid attacks. The CaF₂ formed as a reaction product becomes a pool of fluoride ions for the formation of fluoroapatite (Ca₁₀(PO₄)₆F₂). It is also proved that fluoride ions enhances calcification of tooth, and restores lattice imperfection, and improves the crystallinity of HA.

3. The anti-enzymatic actions of the reaction products between Ag(NH₃)₂F and organic component of the tooth can be the next mechanism of action for caries arrest. Its antibacterial properties arise from inhibition of the enzyme activities and dextran-induced agglutination of cariogenic strains of Streptococcus mutants. Resistance of dentin to trypsin increased when SDF is applied on tooth surface. Also, a study reported that resistance to collagenase and trypsin for dentin protein increased after treating the tooth with SDF.

Clinical Applications
1. For management of patients with high caries prevalence like with xerostomia.
3. To arrest caries in anterior primary teeth of young children- Earlier rampant caries was treated with removal of carious dentin and temporary restoration with zinc oxide eugenol. SDF can provide a better substitute for the such patients of irregular caries pattern.
4. SDF is effective in arresting dentin caries in a Community-based Caries Control Program- SDF can be used to tackle the caries problem in community dental health programs especially in developing and low income countries. The main advantages could be: 
   a. Control of pain and infection with affordable cost.
   b. Simplicity of treatment- so non-professionals can also apply SDF.
   c. Minimal support required so is feasible without piped water and electricity.
   d. Non-invasive procedure, thus the risk of spreading infection is very low.

5. To prevent pit and fissure caries- SDF can be effective for the prevention of pits and fissures caries of the first molar. A study mentioned that fissure caries were less in SDF applied teeth when compared with SnF2 8% or Ag(NO)3. However, because of grayish-black and black stain at the pit and fissure by SDF may be mistaken for incipient caries, so the application should be mentioned appropriately in records.

6. To prevent further caries
7. Annual application of SDF is effective in arresting the root caries.
8. SDF has an ability to occlude the dentinal tubule so is used for dentinal hypersensitivity and 4 times repeated application was suitable for its treatment.
9. To disinfect root canals- SDF can be effectively used as an endodontic irrigant.
10. For the patients who have behavioral or medical management issues.

Contraindications

1. Allergy to silver
2. Pregnancy
3. Breastfeeding
4. Ulcerative gingivitis
5. Stomatitis

Safety

Average LD50 by oral administration is 520 mg/kg, and by subcutaneous administration is 380 mg/kg. One drop (25 μL) is sufficient to treat 5 teeth, and has 9.5 mg SDF. Suppose the child patient can be of 10 kg, the dose would be 0.95 mg / kg child. Hence, the relative safety margin of utilizing a full drop on a 10kg child is: 380 mg/kg LD50 / 0.95 mg / kg dose = 400-fold safety margin.

Procedure to apply SDF
1. Cover the counter with plastic and drape the patient with plastic bib.
2. Standard personal protective equipment to be worn by both patient and Provider.
3. Dispense one drop (25 uL/10kg per treatment visit) of SDF in dappen dish.
4. Isolate and dry the affected teeth / tooth.
5. Apply petroleum jelly on gingiva.
6. Apply SDF on teeth with a smallest micropore.
7. Wait for 1 minute after application and remove the excess with cotton gauge.
8. Rinse with water.
9. Repeat the procedure every 6 months.

Adverse effects

When SDF was applied to several teeth to arrest or prevent dental caries in various interventional studies, the only side effect reported was for 3 subjects who followed for up to 3 years reported “a small, mildly painful white lesion in the mucosa, which disappeared after 2 days without treatment.” No adverse pulpal response was observed.

Non-medical side effects

1. SDF darkens carious lesions.
2. Patients may experience a transient metallic or bitter taste.
3. Little amount of SDF can result in “temporary tattoo” on skin but does no harm. Stain on the skin diminish with the natural skin exfoliation, in 2-14 days.
4. SDF stains clinic surfaces and clothes. Spills to be cleaned up immediately with copious water, ethanol, or bleach.

Effects on bonding of dental materials to tooth

1. SDF had no effect on bonding of composite to non-carious dentin using either self-etch or light cure etch systems.
2. In a study, rinsing with water after SDF application prevented a 50% decrease in bond strength for GIC. In another study, increased dentin bond strength to GIC was observed.
3. SDF decreased dentin bonding strength of resin-based crown cement by ~1/3. As a result, rinsing will be adequate for direct restorations, while removal of the SDF treated superficial dentin will be advisable for cementing crowns.

Conclusion

Application of SDF biannually is better than all other minimally invasive treatment choices. However, it is unclear what will happen if treatment is stopped after 2-3 years and further research is required. SDF is more effective as a primary preventive material than other restorative materials which are available, except dental sealants which are >10 times more costly and needs professional follow up.

The use of SDF as a preventive or therapeutic modality can prevent or delay dental treatment for all age groups. It can easily replace fluoride varnish for the caries arrest in subjects that have active caries. It is a
powerful public health tool in the fight against dental caries especially in low income countries.
