Abstract

Introduction: The clavicle is most frequently and easily fractured bone, due to direct blow or fall on the outstretched hand. With changing trends in treatment of midshaft clavicle fractures, plating was one of the standard procedures. Recent attraction for treatment of midshaft clavicle fracture is the titanium elastic nailing system (TENS). Due to lack of prospective studies, the present study was undertaken to assess the effectiveness of minimally invasive method TENS for the treatment of midshaft clavicle fracture.

Materials and Methods: The study population included 30 patients exclusively with fracture of midshaft clavicle on plain radiographs from January 2014 to June 2015 at a tertiary care center. Most of cases were operated within 24-48 hours after trauma. Intra operatively, image intensifier was used for monitoring the manipulations and maneuvering of the nails for closed reductions of the fractures. Patients were followed for 6 months postoperatively and then titanium nails were removed.

Result: Average age of the study population was 35.8 ± 10 yrs. Most cases were operated within 24-48 hours after trauma. In 24 cases, closed reductions and nailing were done, while in 6 cases, open reductions and nailing were done. Constant score was used to assess the clinical outcome of our patients after union of the fracture. Clinical union was achieved in 3-5 weeks, while radiographic union was achieved in 6-8 weeks. There was no post-operative infection in this study.

Conclusion: Operative interventions with TENS showed better results in regards to early functional recovery. The specific advantages of TENS over plating are that it is minimally invasive, needs lesser operative time, and early mobilization.

Keywords: Clavicle fracture, Titanium Elastic Nailing (TENS), Closed reduction, Open reduction.

Introduction

The clavicle is most frequently and easily fractured bone, due to direct blow or fall on the outstretched hand. Among all fractures, incidence of clavicle fractures was contributed to 3-5%.1 Various treatment techniques are available for clavicular fractures.1,8 An operative approach in trend, which consists of two main procedures namely open reduction & plating; and by intramedullary nailing through minimal access.1,3,5,8 Though plating technique is accepted as a standard technique, it has some disadvantages like large scar, higher non-union rate and difficult application as well as problem with removal.1 Whereas, intramedullary nailing of clavicular fractures is done by numerous techniques and multiple devices2,6,9-11 which have their own advantages and disadvantages.1,6,8,10 Nowadays, due to breakage and migration of the plate, rigid fixation is not used.10,12

First time a new technique Titanium Elastic Nail Systems (TENS) was presented by Jubel et al and currently it’s being advocated though there are different opinions about its uses.13,14 Because of less complications, rapid union rate, easy insertion and removal, small scar and lack of breakage, some authors have recommended for its use.6,14

Keeping above facts in mind, the present study was undertaken to assess the effectiveness of minimally invasive method Titanium Elastic Nails (TENS) for the treatment of midshaft clavicle fracture.

Materials and Methods

The present study was conducted from January 2014 to June 2015 at a tertiary care center. The study population included 30 patients exclusively with fracture of midshaft clavicle on plain radiographs. Titanium Elastic Nails used in this study were comparatively cheaper as compared to plates and affordable to poor patients. Intra operatively image intensifier was used for monitoring the manipulations and maneuvering of the nails for closed reductions of the fractures.

Inclusion Criteria: Clavicular mid-shaft fractures with displacement of fragments more than 2 cm on plain radiographs, clavicular length shortening more than 2 cm on plain radiographs, comminuted fractures, ipsilateral upper extremity injuries / fracture, multiple ipsilateral upper ribs fractures, floating shoulder and fresh closed mid-shaft clavicular fractures.

Exclusion Criteria: Old fractures, open fractures, proximal end and distal end fractures and pediatric age group (< 12yrs).

Technique: Supine position was given on radiolucent table with small bolster beneath the scapula on operating side with C arm at head end. Incision was made 2 cm lateral to sternoclavicular joint, and entry was made in the anterior cortex of the bone by a small bone awl. Proper anterior-posterior (AP), caudal & cranial views were taken throughout the procedure15 (Fig. 1).
Fig. 1: Antegrade flexible nailing of midshaft clavicle fractures

A size 2-3 mm titanium elastic nail is inserted from medial end and passed through the fracture site and advanced until the tip of the nail was engaged in superolateral cortex of lateral end of clavicle (Fig. 2).

Fig. 2: Entry point

If the medullary canal is very narrow, small hand reamers were used first to ream the canal and then nail was inserted. In few cases, another small incision was made at fracture site and lateral end was reamed to help fracture fixation (Fig. 3).

Fig. 3: Intra-operative pictures

Clavicular fracture was protected by standard sling for comfort and pendulum exercises were allowed in the immediate post-operative period. Patients were permitted for free shoulder movement as much as they could during the postoperative period. Sutures were removed on 12th postoperative day and x-rays done at 6 weeks (Fig. 4(A) & 4(B)).

Fig. 4: Pre-operative x-ray

Overhead activity was restricted for 3 weeks. After 6 weeks when radiological union was seen, strengthening exercises were started. In this study, all the fractures healed in 6 to 8 weeks postoperatively. Patients were followed for 6 months postoperatively and then titanium nails were removed (Fig. 5 & 6).

Fig. 5: After six months follow up

Fig. 6: Small scar at entry point
Constant shoulder score was used to assess the clinical outcome of our patients. It contains a questionnaire in which pain, activity level, arm positioning, strength of abduction, forward flexion, lateral elevation, external rotation and internal rotation are measured. The results are based on the score, > 30-Poor, 21–30-Fair, 11–20-Good, < 11-Excellent

Statistical Analysis: Descriptive statistics such as mean, SD and percentage was used to present the data. Microsoft excel was used to prepare the tables and graphs.

Results

Total 30 cases were included, out of which 20 were male and 10 were female patients. Among these, 20 patients had right sided clavicular fractures and 10 patients had left sided fractures. Average age of the study population was 35.8 ± 10 yrs. Most cases were operated within 24-48 hours after trauma. In 24 cases, closed reductions and nailing were done, while in 6 cases, open reductions and nailing were done. Titanium Elastic Nails used in this study were comparatively cheaper as compared to plates and affordable to poor patients.

Mid shaft clavicular fractures having displacement less than 2 cm were excluded from this study and were treated conservatively. Fractures with displacement between 2-5 cms were operated by closed reduction and nailing, while fractures with displacement more than 5 cms were operated by open reduction and nailing.

To assess the clinical outcome of our patients after union of the fracture, constant score was used. Clinical union was achieved in 3-5 weeks, while radiographic union was achieved in 6-8 weeks with average 6.9 ± 0.9 weeks. There was no post-operative infection in this study.

Three cases had medial migration of titanium nails at 6 weeks, but callus had already begun to form. There was no case of non-union. Six patients had scars at both the entry points and fracture sites. The remaining 24 patients had about 1 cm scars only at the entry points.

Table 1: Age distribution

<table>

Most of cases of extent of displacement of fractures were belongs to 2-5 cms (80%)

Discussion

Clavicular fractures are very frequent and account for approximately 2.6% of all fractures, majority of them (80-85%) occur in the midshafts.

OTA (Orthopaedic Trauma Association) classification of midshaft clavicular fractures is as follows: A type - Simple fractures, two fragments, B type - Fractures with a bending wedge, C type - Complex fractures.

TENS is a very simple and reliable technique in fixation of displaced midshaft clavicular fractures. Operative time is 25-30 minutes which is less as compared to plating where 55-60 minutes is needed.

The strength of this study is that with minimal invasive technique, midshaft clavicular fractures are fixed by closed nailing or minimal open reduction at fracture site.

The limitations of this study were the need of image intensifier to confirm the position of nail and a radiolucent table.

This method of management of midshaft clavicular fractures has got many advantages over open reduction and plating like minimally invasive technique, less operative time, decreased postoperative morbidity, faster recovery and cosmetically better scar.

The present study shows that management of midshaft clavicular fractures treated by closed nailing is definitely a novel approach. Titanium nails are cheaper as compared to plates and easily affordable to poor patients. TENS would be choice of treatment modality in midshaft clavicular fractures displaced more than 2 cms and patients requiring early mobilization in form of overhead activity and early return to his normal activities. Overhead activity was started 3 weeks postoperatively. With conservative methods, patients have to wear clavicular braces for minimum of six weeks, delaying rehabilitation programme.

Duan and his colleagues concluded that there were no significant differences of outcomes between plating
