Abstract
Mastitis is the most important disease in dairy farms worldwide causing significant economic losses. Sixty milk samples were collected from mastitic cows and submitted to the laboratory for further bacteriological examinations. Staphylococcus spp. (45%), Bacillus spp. (22.5%), Enterobacter spp. (14.5%), Pseudomonas spp. (8%), Acinetobacter spp (5%) and Micrococcus spp (5%) were found in bacteriological examination of all milk samples. Staphylococcus aureus was the most prevalent among Staphylococci isolates (45%), followed by Staphylococcus intermedius (22%), Staphylococcus warneri (11%), Staphylococcus hyicus (11%), Staphylococcus chromogenes (11%) and Staphylococcus lentus (11%) Also Bacillus spp were found to be: Bacillus alvei (40%) Bacillus thermophilus (20%), Bacillus coagulans (20%) and Bacillus firmus (20%). Sensitivity tests were conducted using 12 different antibiotics including Tetracycline and Gentamicin. The sensitivity was determined for each antibiotic by using disc diffusion technique according to Kirby–Bauer method. The isolated bacteria were highly sensitive to Ciprofloxacin, Iflovulxten, Linezolid, Gentamicin and they were found to be resistant to Cloxacillin, Cephalaxin, Followed by Tetracycline, Lincomycin. Roxithromycin. This study showed that the most causative agent of mastitis in south Khartoum is Staphylococcus aureus. Hygienic practices procedure in dairy farm must be sustainable to reduce this disease and to be aware about the suitable antibiotics to be used using antibiotic sensitivity test. The present study was designed to investigate the sensitivity of different antibiotics against bacteria isolated from suspected mastitic cows in dairy farms in south Khartoum, Sudan.

Keywords: Staph. aureus, Bacillus, Antibiotics, Mastitis, Ciprofloxacin, Sensitivity.

Introduction
Mastitis is the inflammatory disease of mammary glands of ruminants which may cause partial or full damage to udder leading to permanent blocking of milk ducts. It is the most common reason for the use of antimicrobials in dairy cows. Antibiotics have been used to treat mastitis for more than fifty years, but consensus about the most efficient, safe, and economical treatment is still lacking.3

Gentamicin is used extensively in the management of acute coliform mastitis, because > 90% of coliform isolates are susceptible to this drug in-vitro. Intramammary administration of gentamicin results in minimal inhibitory concentrations in milk. The efficacy of intramammary gentamicin as a treatment for acute coliform mastitis has not been studied, and the amount of gentamicin that diffuses into plasma after intramammary infusion during an acute infection is unknown.4

Tetracycline is one of the most extensively used antibiotics because of its relative safety, low cost, and broad-spectrum activity against Gram-positive, Gram-negative bacteria, and a typical organisms such as Mycoplasma. However, therapeutic outcomes generally do not match the results from in-vitro susceptibility tests for mastitis causing pathogens, this inefficacy has been considered to be due to some factors such as the limited knowledge of pharmacokinetic properties of tetracycline in lactating dairy cows, decreased antibiotic activity in the milk phase, and the appearance of resistant bacteria. It is difficult to produce and maintain therapeutic concentrations in the milk with many commonly used broad-spectrum antimicrobials such as oxytetracycline, trimethoprim-sulphonamide and cefotiofur.7,8

This study was aimed to evaluate the efficacy of some antibiotics against different isolated bacteria from suspected mastitic cows in dairy farm in south Khartoum, Sudan.

Materials and Methods
Sampling
Sixty samples were collected from suspected mastitic cows, clinical and chronic mastitis cases. Milk samples were taken under aseptic conditions and submitted to the laboratory for further bacteriological studies. Five ml of milk were collected in sterile disposable bottles. Identification and biochemical tests were done.9

Sensitivity tests
The sensitivity was determined by using disc diffusion technique according to Kirby–Bauer method.10 Commercially prepared antibiotic disc from different concentrations for each antibiotic: Ampicillin/subbactam (AS) 30mcg, Levofoxacin (LE) 5 mcg, Linezolid (LZ) 30mcg, Co-Trimoxole (BA) 25mcg, Cephalaxin (PR) 30mcg, Cl oxacillin (CX) 5mcg, Tetracycline (TE) 30mcg, Roxithromycin (RF) 15mcg, Cefotaxime (cf) 30mcg, Lincomycin (LM) 2mcg, Ciprofloxacin (CP) 5mcg and Gentamycin (GM) 10mcg.

The disks were placed onto the surface of the diagnostic sensitivity test medium inoculated with the isolated bacteria suspension. The plates were then incubated at 37°C for 48 hour.
The zones of inhibitions were measured using the average of diameter inhibition zone in millimeters (ADIZ).

**Results**
Bacteriological examination of all milk samples found the presence of: Staphylococcus spp. (45%), Bacillus spp. (22.5%), Enterobacteria spp (14.5%), Pseudomonas spp (8%), Acinobacter spp (5%) and Micrococcus spp (5%). *Staphylococcus aureus*, was the most prevalent among Staphylococci isolates (45%), followed by *Staphylococcus intermedius* (22%), as it has been shown in Fig. 1.

Results of identification of Bacillus spp were shown in Fig. 2.

![Fig. 1: Percentage of types of Staphylococcus spp isolated from mastitic cows](image1)

![Fig. 2: Percentage of types of bacillus SPP isolated from mastitic cows](image2)

**Sensitivity test**
The inhibition zone results against different antibiotic was shown in table 1 and Fig. 3). All isolated bacteria were found to be highly resistant to Gentamyacin. Tetracycline showed low efficacy and it had a highly percentage of resistant. Ciprofloxacin is the most effective antibiotic (100%), this result makes it the drug of choice to treat mastitis cases in dairy cattle.

Sensitivity of Bacillus spp. was found to be as 70% for Gentamycin and 30% for Tetracycline this finding was in agreement with other reports. 

In this study, Ciprofloxacin, Norfloxacin, Gentamicin and Streptomycin were found to be more effective against all isolated bacteria. These results are in agreement and supported with other report. 

While other researchers found that the isolates showed the highest resistance towards Penicillin, Collaxacillin, Clindamycin and Ampicillin but Chloramphenicol showed the highest antimicrobial activity followed by Pipercillin and Gentamicin.

Sensitivity of Bacillus spp. was found to be as 70% for Gentamycin and 30% for Tetracycline this finding was in agreement with different research.

In previous studies, the sensitivity of numerous bacteria isolated from mastitic milk of cows to Penicillin, Amoxicillin and Tetracycline is in contrast to our result in this study. This might be due to absence of resistant strains.

**Discussion**

In this study, *Staphylococcus aureus* was the most frequent isolated pathogen (50%). This might be attributed to the survival of this bacterium in variety environments. This result is in agreement with. The high incidence in our study might be attributed to increasing of numbers of animals per farm and also due to the spread of resistant strains.

While the isolation of *Klebsiella* spp., *Enterococcus* spp (10%), *E.coli* and *Enterobacter* spp. is attributed to poor hygiene. The failure of sanitary programme help the recovery of *Bacillus* spp., this suggestion is supported by other authors. The contribution of *Pseudomonas* spp in the causation of mastitis in this study is in agreement with other reports.

In this study, Ciprofloxacin, Norfloxacin, Gentamicin and Streptomycin were found to be more effective against all isolated bacteria. These results are in agreement and supported with other report. While other researchers found that the isolates showed the highest resistance towards Penicillin, Collaxacillin, Clindamycin and Ampicillin but Chloramphenicol showed the highest antimicrobial activity followed by Pipercillin and Gentamicin.

In previous studies, the sensitivity of numerous bacteria isolated from mastitic milk of cows to Penicillin, Amoxicillin and Tetracycline is in contrast to our result in this study. This might be due to absence of resistant strains.

**Conclusion**

It is concluded that the control of mastitis is an integrated procedures including, detection, identification of aetiological agents, proper treatment, proper sanitary measurements and proper veterinary services. If any of the above mentioned steps is overlooked this may lead to the spread of mastitis.
